ABSTRACT: Bacterial phytases and phytase-producing bacteria are of great industrial significance in the poultry industry and also in phosphorus pollution management. This study was designed to isolate and screen for phytase producing lactic acid bacteria from the duodenum, ileum and cecum of eight healthy cockerel samples. Standard microbiological procedures were followed to isolate phytase producing lactic acid bacteria using de Man Rogosa and Sharp (MRS) agar while extracellular phytase screening was done using phytase specific medium. The range of total microbial count obtain was highest at the cecum (2.85 ± 0.11 to $4.34 \pm 0.12 \log_{10}$ cfu/ml), lower at the duodenum (2.02 ± 0.11 to $4.27 \pm 0.20 \log_{10}$ cfu/ml) and lowest at the ileum (2.00 ± 0.21 to $4.19 \pm 0.25 \log_{10}$ cfu/ml). Nineteen bacterial isolates were identified as lactic acid bacteria on the basis of morphological, biochemical and physiological characterization and later identified as *Lactobacillus* species (78.94%), *Enterococcus* species (15.78%) and *Lactococcus* species (5.26%). Thirteen out of the nineteen lactic acid bacteria showed phytase activity. Low phytase activity was observed in eight of the lactic acid bacteria isolates while five of the isolates produced significant extracellular phytase activity (>6mm). The most predominant *Lactobacillus* species were also found to be the most potent phytase producers. This can be exploited for industrial production of phytase in upgrading the nutritional status of feed and combating phosphorus pollution from poultry waste.

Keywords: Phytase, Gastrointestinal tract, Lactic acid bacteria, Phosphorus pollution, Poultry industry.

INTRODUCTION

Phosphorus is an important nutrient stored in the form of phytic acid (*Myo-inositol 1,2,3,4,5,6-hexakis dihydrogen phosphate*) in cereals, legumes, and oilseed crops (Azeke et al., 2007). Phytic acid acts as antinutrient constituent in plant-derived food and feed as it forms complexes with proteins, amino acids, and various metal ions (Astley and Finglas, 2016; Nissar et al., 2017). The bound phosphorus is poorly available to monogastric animals such as pigs, poultry and fishes, due to lack of production of phytases in the gastrointestinal tract (Jacela et al., 2010; Abdel-Megeed and Tahir, 2015). Excretion of the undigested phytate poses a serious phosphorus pollution problem contributing to eutrophication in areas of intensive livestock production (Singh et al., 2011; Abdel-Megeed and Tahir, 2015). The enzyme phytase hydrolyzes the ester bond in phytic acid to liberate inositol and inorganic phosphate (Nissar et al., 2017). It can be sourced from some plants, animal tissues and microorganisms; microbial sources are however more promising for the commercial production of phytases (De Angelis et al., 2003).

Phytases have been obtained mainly from filamentous fungi (Maller et al., 2013); it has also been detected in various bacteria species such as *Bacillus*, *Pseudomonas*, *Escherichia coli*, *Enterobacter*, *Klebsiella*, *Lactobacillus sanfranciscensis* as well as anaerobic rumen bacteria, particularly in *Selenomonas ruminantium*, *Megasphaera elsdenii*, *Prevotella* sp., *Mitsuokella multiacidus* and *Mitsuokella jalaludinii* (Shim and Oh, 2012).

Species of lactic acid bacteria (LAB) belonging to numerous genus under the family of *Lactobacillaceae* have been widely applied in food fermentation worldwide due to their widely known status as generally recognized as safe (GRAS) microorganisms (Hayek and Ibrahim, 2013). They are also recognized for their fermentative ability which contributes to enhancing food safety, improving organoleptic attributes, enriching nutrients and increasing health benefits (Sharma et al., 2012; Steele et al., 2013). There are only few reports of phytase producing lactic acid bacteria available in literature, therefore this present study was designed to isolate phytase producing lactic acid bacteria from the gastrointestinal tract of poultry. The addition of phytase to poultry feed will improve the nutritional quality of feed by increasing the amount of free phytate phosphorus in poultry diet and diminishing the necessity of addition of inorganic phosphate to animal feed, thereby combating phosphorus pollution associated with the feed and poultry industries.

MATERIALS AND METHODS

Ethical Approval

The Ethics Unit of the Research and Innovation Committee of Samuel Adegboyega University approved the study protocol.

Study Area

The study was carried out at College of Basic and Applied Sciences, Samuel Adegboyega University, Ogwa in Esan West Local Government Area of Edo State, Nigeria.

Sample collection and preparation

Eight cockerels were purchased from Global Poultry, Uromi, Esan North East Local Government Area, Edo State, Nigeria. The gastrointestinal tracts of the eight chickens were aseptically collected in ten sterile plastic bags and transported to the laboratory in ice packs for microbiological analysis. The samples were represented with codes A-H. The duodenum, ileum and cecum represented with codes d, i and c for each of the eight samples were removed separately under sterile conditions to give a total of twenty-four samples.

Enumeration and isolation of bacteria

Ten grams of the duodenum, ileum and cecum respectively for each sample was weighed aseptically and transferred into a sterile beaker containing 100ml of normal saline. Six-fold serial dilution (10^{-1} to 10^{-6}) was made using normal saline. An aliquot of 1 ml of the appropriate six-fold serial dilution (10^{-2}) of the intestinal samples were inoculated into the de Man Rogosa and Sharp (MRS) agar plates using standard pour plate method and incubated anaerobically at 37 °C for 36 hours. Visible discrete colonies on inoculated plates were counted using the colony counter and expressed in colony forming units per millilitre (cfu/ml) of the intestinal sample. Discrete colonies were selected and purified by subculturing in MRS broth. Further purification was carried out by repeated streaking on freshly prepared MRS agar plates. The pure isolates were stored at 4 °C using MRS agar slants.

Characterization and identification of bacterial isolates

Pure cultures of all isolates were characterized and identified by means of their cultural, morphological, physiological and biochemical characteristics using Bergey's manual of systematic Bacteriology (Holt et al., 1994)

Phytase activity screening

The isolated pure strains were screened for the production of extracellular phytase using phytase specific medium (Chunshan et al., 2001). The phytase screening medium was prepared by dissolving 3g glucose; 1g Tryptone; 1g sodium phytate; 0.3g CaCl₂; 0.5g MgSO₄; 0.04g MnCl₂; 0.0025g FeSO₄; and 15g agar in 1 litre of distilled water. The pure cultures were streaked at the centre of the plate and the plates were incubated at 37°C for 62 hours as described by Kumar et al. (2011). The plates were then observed for formation of clear zone around the colony. A clear zone around the colony indicates positive result. Only those with zones greater than 6mm in diameter were recorded as significant.

Data analysis

The mean, standard error of mean, one way ANOVA and Tukey's Post Hoc analysis were done using IBM SPSS Statistics 23 software for Windows. P value < 0.05 was statistically significant.

RESULTS

The total bacterial count from the duodenum, ileum and cecum of the eight chicken samples are presented in Table 1. A total of fifty-seven bacteria isolates were randomly selected based on distinct colony morphology and purified. The morphological, physiological and biochemical characteristics of the pure isolates revealed that 49.12% of the bacterial isolates were white, viscous, entire, glistening and raised. 10.53% were creamy, viscous, entire, glistening and flat. 26.32% were white, viscous, entire, glistening and raised. 12.28% were white, dry, entire, rough and raised. 1.75% were creamy, viscous, entire, glistening and raised. Nineteen out of the fifty-seven bacterial isolates were presumed as lactic acid bacteria on the basis of gram stain reaction, catalase production and oxidase activity. The isolates were gram positive short rods and cocci, catalase negative and oxidase negative. Further presumptive tests including growth at temperature 10°C and 45°C, growth at pH 4.5 and 6.5, gas production from glucose and ability to ferment various carbohydrates (lactose, maltose, sucrose and glucose) performed indicated that growth was recorded for all the isolates at pH 4.5 and pH 6.5 at 45°C only. The isolates were identified as *Lactobacillus*, *Lactococcus* and *Enterococcus* species. The percentage occurrence of the lactic acid bacteria isolates is shown in Figure 1. Thirteen out of the nineteen lactic acid bacteria isolates showed phytase activity by hydrolyzing sodium phytate to form a clear zone around the colony (Table 2). Five bacterial isolates, all *Lactobacillus* species, (Dc2, Dd2, Dd4, Fd1 and Fc3) had a significantly different ($p < 0.05$) ability to hydrolyze phytate by forming a clear zone > 6mm.

Table 1 - Total bacterial counts (Log₁₀ cfu/ml) from the gastrointestinal tracts of samples.

Sample	Duodenum	Ileum	Cecum
A	2.02 ± 0.11	-	2.85 ± 0.11
B	2.26 ± 0.17	2.00 ± 0.21	3.88 ± 0.14
C	3.77 ± 0.12	2.98 ± 0.25	-
D	4.27 ± 0.20	4.11 ± 0.20	3.37 ± 0.14
E	2.03 ± 0.15	3.23 ± 0.22	4.34 ± 0.11
F	2.57 ± 0.38	4.05 ± 0.13	3.53 ± 0.12
G	3.57 ± 0.37	4.19 ± 0.25	3.90 ± 0.18
H	3.85 ± 0.33	3.65 ± 0.25	3.69 ± 0.11

Values are mean ± standard error of mean of triplicate determinations. - = Absent, A-H = Isolation codes for the 8 chicken samples.

Table 2 - Phytase screening of lactic acid bacteria from the gastrointestinal tract of poultry samples

S/N	Isolation code	Hydrolysis of phytate	Clear zone (mm)	Probable bacterial species
1	Ad1	+	5.13 ± 1.02 ^a	<i>Lactococcus</i>
2	Bc1	+	3.24 ± 0.86 ^b	<i>Lactobacillus</i>

DISCUSSION

The bacteria growth recorded in the duodenum, ileum and cecum of all the chicken samples had different growth count range (Table 1). The variation in the microbial population suggests that each region developed its own unique bacterial community due to the pH of the stomach contents, the toxicity of bile salts, fermentative metabolism and the relatively swift flow of the digesta in the gastrointestinal tract (Walter, 2008). This result agrees with the findings of other researchers available in literature. Jiangrang et al. (2003) reported differences in the diversity of bacterial floras in the ilea and ceca of maturing broiler chickens; Bjerrum et al. (2006) investigated microbial communities in the ileum and cecum of broiler chickens, they reported that lactobacillus species dominated the chicken ileum while the cecum harbored more diverse microbial community and Abbas et al. (2007) identified various levels of abundance of different lactobacillus species from the crop of 1- and 5- week old broiler chickens using 16s rRNA gene sequence.

The isolates were identified as *Lactobacillus* species, *Lactococcus* species and *Enterococcus* species. Previous studies confirm the existence of these organisms in the gastrointestinal tract of chicken (Lan et al., 2003; Sonplang et al., 2007). The *Lactobacillus* species were more dominant because of their ability to adhere to the surface of the non-secretory epithelium lining of these sites, which enables the bacteria to form a biofilm-like structure that provides a bacterial inoculum of the digesta (Salas-Jara et al., 2016). Different studies on the microbiota of the gastrointestinal tract of poultry have pointed out the predominance of lactobacilli in chicken crops and intestine (Beasley et al., 2004; Bakari et al., 2011).

Thirteen out of the nineteen lactic acid bacteria showed phytase activity, suggesting that they could be a potential source of phytase to be used in improving the nutritional quality of poultry diet and decreasing the amount of phosphorus released to the environment (Hill et al., 2007; Abdel-Megeed and Tahir, 2015). Five of the *Lactobacillus* species were found to be the most potent phytase producers. Phytase producing ability of lactic acid bacteria has also been reported in some previous studies. Raghavendra and Halami (2009) isolated forty lactic acid bacterial strains with phytate degrading ability while Anastasio et al. (2010) reported the use of lactic acid bacteria to improve mineral solubilization during dough fermentation due to their production of phytate-degrading enzymes.

CONCLUSION

In this study, phytase producing lactic acid bacteria were isolated from the gastrointestinal tract of healthy cockerels. These findings can be further explored in the industrial production of phytase. It will be of immense benefit to the poultry industry. Feed supplementation with phytase will help to improve the nutritional status of the feed. This also has implication for environmental management as it would lead to a reduction in phosphorus pollution.
